Subsetting Data in R

Introduction to R for Public Health Researchers

Overview

We showed one way to read data into R using read_csv and read.csv. In this module, we will show you how to:

- 1. Select specific elements of an object by an index or logical condition
- 2. Renaming columns of a data.frame
- 3. Subset rows of a data.frame
- 4. Subset columns of a data.frame
- 5. Add/remove new columns to a data.frame
- 6. Order the columns of a data.frame
- 7. Order the rows of a data.frame

Setup

We will show you how to do each operation in base R then show you how to use the dplyr package to do the same operation (if applicable).

Many resources on how to use dplyr exist and are straightforward:

- https://cran.rstudio.com/web/packages/dplyr/vignettes/
- https://stat545-ubc.github.io/block009_dplyr-intro.html
- https://www.datacamp.com/courses/dplyr-data-manipulation-r-tutorial

The dplyr package also interfaces well with tibbles.

Select specific elements using an index

Often you only want to look at subsets of a data set at any given time. As a review, elements of an R object are selected using the brackets ([and]).

For example, x is a vector of numbers and we can select the second element of x using the brackets and an index (2):

```
x = c(1, 4, 2, 8, 10)

x[2]
```

Select specific elements using an index

We can select the fifth or second AND fifth elements below:

```
x = c(1, 2, 4, 8, 10)

x[5]

[1] 10

x[c(2,5)]

[1] 2 10
```

Subsetting by deletion of entries

You can put a minus (–) before integers inside brackets to remove these indices from the data.

```
x[-2] # all but the second
[1] 1 4 8 10
```

Note that you have to be careful with this syntax when dropping more than 1 element:

```
x[-c(1,2,3)] # drop first 3

[1] 8 10

# x[-1:3] # shorthand. R sees as -1 to 3
x[-(1:3)] # needs parentheses

[1] 8 10
```

Select specific elements using logical operators

What about selecting rows based on the values of two variables? We use logical statements. Here we select only elements of x greater than 2:

```
x
[1] 1 2 4 8 10

x > 2
[1] FALSE FALSE TRUE TRUE

x[ x > 2 ]
[1] 4 8 10
```

Select specific elements using logical operators

You can have multiple logical conditions using the following:

- · &:AND
- · |: OR

```
x[x > 2 \& x < 5]
```

[1] 4

$$x[x > 5 | x == 2]$$

[1] 2 8 10

which function

The which functions takes in logical vectors and returns the index for the elements where the logical value is TRUE.

```
which(x > 5 | x == 2) # returns index
[1] 2 4 5

x[ which(x > 5 | x == 2) ]

[1] 2 8 10

x[ x > 5 | x == 2 ]

[1] 2 8 10
```

Creating a data. frame to work with

Here we use one of the datasets that comes with R called mtcars create a toy data.frame named df using random data:

```
data(mtcars)
df = mtcars
tbl = as.tbl(df)
```

Renaming Columns

Renaming Columns of a data. frame: base R

We can use the colnames function to directly reassign column names of df:

Renaming Columns of a data.frame: base R

We can assign the column names, change the ones we want, and then re-assign the column names:

Renaming Columns of a data. frame: dplyr

library(dplyr)

Note, when loading dplyr, it says objects can be "masked". That means if you use a function defined in 2 places, it uses the one that is loaded in **last**.

Renaming Columns of a data. frame: dplyr

For example, if we print filter, then we see at the bottom namespace:dplyr, which means when you type filter, it will use the one from the dplyr package.

```
filter

function (.data, ...)
{
    UseMethod("filter")
}
<environment: namespace:dplyr>
```

Renaming Columns of a data.frame: dplyr

A filter function exists by default in the stats package, however. If you want to make sure you use that one, you use PackageName::Function with the colon-colon ("::") operator.

```
head(stats::filter,2)
```

```
1 function (x, filter, method = c("convolution", "recursive"),
2    sides = 2L, circular = FALSE, init = NULL)
```

This is important when loading many packages, and you may have some conflicts/masking:

Renaming Columns of a data.frame: dplyr

To rename columns in dplyr, you use the rename command

Lab Part 1

Website

Subsetting Columns

Subset columns of a data. frame:

We can grab the carb column using the \$ operator.

df\$carb

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

Subset columns of a data. frame:

We can also subset a data.frame using the bracket [,] subsetting.

For data.frames and matrices (2-dimensional objects), the brackets are [rows, columns] subsetting. We can grab the x column using the index of the column or the column name ("carb")

```
df[, 11]

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

df[, "carb"]

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2
```

Biggest difference between tbl and data.frame:

Mostly, tbl (tibbles) are the same as data.frames, except they don't print all lines. When subsetting only one column using brackets, a data.frame will return a vector, but a tbl will return a tbl

```
df[, 1]
 [1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2
[15] 10.4 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4
[29] 15.8 19.7 15.0 21.4
tbl[, 1]
# A tibble: 32 x 1
    mpg
   <dbl>
 1 21.0
 2 21.0
 3 22.8
 4 21.4
 5 18.7
 6 18.1
 7 14.3
 8 24.4
 9 22.8
10 19.2
                                                                       22/55
# ... with 22 more rows
```

Subset columns of a data.frame:

We can select multiple columns using multiple column names:

```
df[, c("mpg", "cyl")]
```

	mpg	cyl
Mazda RX4	21.0	6
Mazda RX4 Wag	21.0	
Datsun 710	22.8	
Hornet 4 Drive	21.4	
Hornet Sportabout	18.7	8
Valiant	18.1	
Duster 360	14.3	
Merc 240D	24.4	
Merc 230	22.8	
Merc 280	19.2	
Merc 280C	17.8	
Merc 450SE	16.4	
Merc 450SL	17.3	
Merc 450SLC	15.2	8
Cadillac Fleetwood		8
Lincoln Continental		8
Chrysler Imperial	14.7	8
Fiat 128	32.4	
Honda Civic	30.4	
Toyota Corolla	33.9	
Toyota Corona	21.5	
Dodge Challenger	15.5	8

Subset columns of a data.frame: dplyr

The select command from dplyr allows you to subset

select(df, mpg)

Mazda RX4 Mazda RX4 Wag Datsun 710 Hornet 4 Drive Hornet Sportabout Valiant Duster 360 Merc 240D Merc 230 Merc 280 Merc 280C Merc 450SE Merc 450SE Merc 450SL Cadillac Fleetwood Lincoln Continental Chrysler Imperial Fiat 128 Honda Civic	10.4 14.7 32.4 30.4

Select columns of a data.frame: dplyr

The select command from dplyr allows you to subset columns of

select(df, mpg, cyl)

	mpg	cyl
Mazda RX4	21.0	6
Mazda RX4 Wag	21.0	6
Datsun 710	22.8	4
Hornet 4 Drive	21.4	6
Hornet Sportabout	18.7	8

Subsetting Rows

Subset rows of a data. frame with indices:

Let's select **rows** 1 and 3 from df using brackets:

```
df[c(1, 3),]
```

```
        mpg
        cyl
        disp
        hp
        drat
        wt
        qsec
        vs
        am
        gear
        carb

        Mazda RX4
        21.0
        6
        160
        110
        3.90
        2.62
        16.46
        0
        1
        4
        4

        Datsun 710
        22.8
        4
        108
        93
        3.85
        2.32
        18.61
        1
        1
        4
        1
```

Subset rows of a data. frame:

Let's select the rows of df where the mpg column is greater than 20 or is less than 14. Without any index for columns, all columns are returned:

```
df[df$mpg > 20 | df$mpg < 14, ]
```

	mpg	cyl	disp	hp	drat	wt	qsec			gear	carb
Mazda RX4	21.0	6	160.0	110	3.90	2.620	16.46	0	1	4	4
Mazda RX4 Wag	21.0	6	160.0	110	3.90	2.875	17.02	0	1	4	4
Datsun 710	22.8	4	108.0	93	3.85	2.320	18.61	1	1	4	1
Hornet 4 Drive	21.4	6	258.0	110	3.08	3.215	19.44	1	0	3	1
Merc 240D	24.4	4	146.7	62	3.69	3.190	20.00	1	0	4	2
Merc 230	22.8	4	140.8	95	3.92	3.150	22.90	1	0	4	2
Cadillac Fleetwood	10.4	8	472.0	205	2.93	5.250	17.98	0	0	3	4
Lincoln Continental	10.4	8	460.0	215	3.00	5.424	17.82	0	0	3	4
Fiat 128	32.4	4	78.7	66	4.08	2.200	19.47	1	1	4	1
Honda Civic	30.4	4	75.7	52	4.93	1.615	18.52	1	1	4	2
Toyota Corolla	33.9	4	71.1	65	4.22	1.835	19.90	1	1	4	1
Toyota Corona	21.5	4	120.1	97	3.70	2.465	20.01	1	0	3	1
Camaro Z28	13.3	8	350.0	245	3.73	3.840	15.41	0	0	3	4
Fiat X1-9	27.3	4	79.0	66	4.08	1.935	18.90	1	1	4	1
Porsche 914-2	26.0	4	120.3	91	4.43	2.140	16.70	0	1	5	2
Lotus Europa	30.4	4	95.1	113	3.77	1.513	16.90	1	1	5	2
Volvo 142E	21.4	4	121.0	109	4.11	2.780	18.60	1	1	4	2

Subset rows of a data.frame:

We can subset both rows and colums at the same time:

```
df[ df$mpg > 20 | df$mpg < 14, c("cyl", "hp")]
```

	CV	hp
Mazda RX4		110
Mazda RX4 Wag	_	110
Datsun 710	4	93
Hornet 4 Drive	6	110
Merc 240D	4	62
Merc 230	4	95
Cadillac Fleetwood	8	205
Lincoln Continental	8	215
Fiat 128	4	66
Honda Civic	4	52
Toyota Corolla	4	65
Toyota Corona	4	97
Camaro Z28	8	245
Fiat X1-9	4	66
Porsche 914-2	4	91
Lotus Europa	4	113
Volvo 142E	4	109

Subset rows of a data. frame: dplyr

The command in dplyr for subsetting rows is filter. Try ?filter

```
filter(df, mpg > 20 | mpg < 14)
                                qsec vs am gear carb
            disp
                 hp drat
                         wt
   mpq cyl
  21.0
         6 160.0 110 3.90 2.620 16.46
  21.0 6 160.0 110 3.90 2.875 17.02
  22.8
        4 108.0
                  93 3.85
                          2.320
  21.4
        6 258.0
                110 3.08
                         3.215 19.44
  24.4
        4 146.7
                 62 3.69
                         3.190
  22.8
                 95 3.92 3.150
        4 140.8
  10.4
        8 472.0 205 2.93
                         5.250
        8 460.0 215 3.00 5.424 17.82
  10.4
  32.4
        4 78.7 66 4.08
                         2.200
                               19.47
10 30.4
         4 75.7 52 4.93
                         1.615
                               18.52
11 33.9
         4 71.1 65 4.22
                         1.835
12 21.5
        4 120.1
                  97 3.70 2.465 20.01
13 13.3
        8 350.0 245 3.73
                         3.840
14 27.3
        4 79.0
                 66 4.08
15 26.0
        4 120.3
16 30.4
            95.1 113 3.77 1.513 16.90
        4 121.0 109 4.11 2.780 18.60 1 1
17 21.4
```

Note, no \$ or subsetting is necessary. R "knows" mpg refers to a column of df.

Subset rows of a data. frame: dplyr

By default, you can separate conditions by commas, and filter assumes these statements are joined by &

```
filter(df, mpg > 20 \& cyl == 4)
   mpg cyl disp hp drat
                       wt
                            gsec vs am gear carb
  22.8 4 108.0 93 3.85 2.320 18.61 1
  24.4 4 146.7 62 3.69 3.190 20.00 1
  22.8 4 140.8
               95 3.92 3.150 22.90 1
  32.4 4 78.7 66 4.08 2.200 19.47
                            18.52 1 1
  30.4 4 75.7 52 4.93 1.615
  33.9
       4 71.1 65 4.22 1.835 19.90
 21.5
       4 120.1 97 3.70 2.465 20.01
 27.3 4 79.0 66 4.08
                       1.935 18.90
  26.0 4 120.3 91 4.43
                       2.140
10 30.4 4 95.1 113 3.77 1.513 16.90 1 1
11 21.4 4 121.0 109 4.11 2.780 18.60 1 1
filter(df, mpg > 20, cyl == 4)
          disp hp drat
                       wt
                             gsec vs am gear carb
   mpa cyl
  22.8 4 108.0 93 3.85 2.320 18.61 1
  24.4 4 146.7 62 3.69 3.190 20.00 1 0 4
               95 3.92 3.150 22.90 1 0 4

  32.4
                                                              32/55
  30.4
       4 75.7 52 4.93 1.615 18.52
```

Lab Part 3

Website

Combining filter and select

You can combine filter and select to subset the rows and columns, respectively, of a data.frame:

```
select(filter(df, mpg > 20 & cyl == 4), cyl, hp)

cyl hp
1     4     93
2     4     62
3     4     95
4     4     66
5     4     52
6     4     65
7     4     97
8     4     66
9     4     91
10     4     113
11     4     109
```

In R, the common way to perform multiple operations is to wrap functions around each other in a nested way such as above

Assigning Temporary Objects

One can also create temporary objects and reassign them:

```
df2 = filter(df, mpg > 20 & cyl == 4)

df2 = select(df2, cyl, hp)
```

Using the pipe (comes with dplyr):

11

4 109

Recently, the pipe %>% makes things such as this much more readable. It reads left side "pipes" into right side. RStudio CMD/Ctrl + Shift + M shortcut. Pipe df into filter, then pipe that into select:

Adding/Removing Columns

Adding new columns to a data.frame: base R

You can add a new column, called newcol to df, using the \$ operator:

```
df newcol = df wt/2.2
head (df, 3)
```

```
        Mazda RX4
        Wasda RX4
        <t
```

Removing columns to a data.frame: base R

You can remove a column by assigning to NULL:

```
df$newcol = NULL
```

or selecing only the columns that were not newcol:

```
df = df[, colnames(df) != "newcol"]
head(df,3)
```

```
      Mazda RX4
      21.0
      6
      160
      110
      3.90
      2.620
      16.46

      2.320
      18.61
      1
      1
      4
      1
```

Adding new columns to a data.frame: base R

You can also "column bind" a data.frame with a vector (or series of vectors), using the cbind command:

```
cbind(df, newcol = df$wt/2.2)
```

```
mpg cyl
                            disp
                                  hp drat
                                             wt

Adding columns to a data. frame: dplyr

The mutate function in dplyr allows you to add or replace columns of a data.frame:

```
print(\{df = mutate(df, newcol = wt/2.2)\})
             disp
                                  qsec vs am gear carb
    mpg cyl
                  hp drat
                               wt
                                                            newcol
   21.0
                  110 3.90 2.620
                                  16.46
                                                       4 1.1909091

```

Removing columns to a data. frame: dplyr

The NULL method is still very common.

The select function can remove a column with a minus (-), much like removing rows:

```
select(df, -newcol)

mpg cyl disp hp drat wt qsec vs am gear carb
```

```

Ordering columns

Ordering the columns of a data. frame: base R

We can use the colnames function to get the column names of df and then put newcol first by subsetting df using brackets:

```
cn = colnames(df)
df[, c("newcol", cn[cn != "newcol"]) ]
     newcol mpg cyl disp hp drat wt qsec vs am gear carb
  1.1909091 21.0
                    6 160.0 110 3.90 2.620 16.46
                    6 160.0 110 3.90 2.875 17.02
  1.3068182 21.0
  1.0545455 22.8
                 4 108.0
                            93 3.85 2.320 18.61 1
  1.4613636 21.4
                                    3.215 19.44 1
                    6 258.0
                           110 3.08
                    8 360.0 175
                               3.15

```

Ordering the columns of a data. frame: dplyr

The select function can reorder columns. Put newcol first, then select the rest of columns:

```
select(df, newcol, everything())
      newcol
              mpg cyl
                      disp hp drat
                                         wt
                                              qsec vs am qear carb

```

Ordering the rows of a data.frame: base R

You can pass multiple vectors, and must use the negative (using –) to mix decreasing and increasing orderings (sort increasing on x and decreasing on y):

```
df[ order(df$mpq, -df$hp), ]
                                  qsec vs am gear carb
    mpg cyl
             disp
                  hp drat
                               wt
                                                            newcol
16 10.4
          8 460.0 215 3.00 5.424
                                  17.82
                                                       4 2.4654545
15 10.4
          8 472.0 205 2.93
                           5.250
                                                       4 2.3863636

```

3 1.8500000

Ordering the rows of a data. frame: dplyr

It is a bit more straightforward to mix increasing and decreasing orderings:

```
arrange(df, mpg, desc(hp))
    mpg cyl
             disp
                   hp drat
                                wt
                                    qsec vs
                                            am gear carb
                                                              newcol
   10.4
                       3.00 5.424
                                   17.82
                                                        4 2.4654545
   10.4
                       2.93
                            5.250
                                                        4 2.3863636

Transmutation

20 0.8340909 33.9

21 1.1204545 21.5

65

The transmute function in dplyr combines both the mutate and select functions. One can create new columns and keep the only the columns wanted:

```
transmute (df, newcol2 = wt/2.2, mpq, hp)
    newcol2
             mpg
  1.1909091 21.0
  1.3068182 21.0 110
  1.0545455 22.8
  1.4613636 21.4 110
  1.5636364 18.7 175
  1.5727273 18.1 105
  1.6227273 14.3 245
  1.4500000 24.4
  1.4318182 22.8
10 1.5636364 19.2 123
11 1.5636364 17.8 123
12 1.8500000 16.4 180
13 1.6954545 17.3 180
14 1.7181818 15.2 180
15 2.3863636 10.4 205
16 2.4654545 10.4
17 2.4295455 14.7 230
18 1.0000000 32.4
19 0.7340909 30.4
                   52
```
